Core Question

How do we take others' visual perspectives?

- Do we **reconstruct** what others actually see (*perceptual simulation*)? Or do we **infer** it using *heuristic rules* about vision?
- **Explicit VPT** favors *heuristic* accounts — but **implicit VPT** remains unresolved.

Key Hypothesis

But why does simulation seem to fail?

- Simulation may not fail because it can't, but the **agent's perspective is unknown**.
- **Test different priors in implicit VPT:**
 - *Perceptual Simulation Account* predicts bias only with correct priors.
 - *Heuristic inference* predicts bias even with incorrect priors.

Conclusion

- **Implicit VPT remains best explained by *heuristic inference* rather than *perceptual simulation*.**
- Judgments are biased by both correct and incorrect priors (Exp. 1a), and this bias is not driven by priming (Exp. 1b), ruling out simulation-based reconstruction.
- Heuristic inference is plausibility-weighted, integrating prior information with self-viewed input, while extreme priors are discounted (Exp. 2).
